A: Try this - -pdo_mysql=/usr/local/mysql/lib/libmysql.so.10 -pdo_mysql.default_socket=/usr/local/mysql/var/mysql/mysql.sock -pdo_mysql.default_socket=/usr/local/mysql/var/mysql/mysql.sock -pdo_mysql.cache_size=0 Source : Limited proteolysis of mouse Fc receptors from B cells, erythrocytes, and mast cells. Protease digestion of the mouse IgG2b and IgE class of immunoglobulins and of the mouse IgM class of immunoglobulins leads to the inactivation of the corresponding Fc receptors. The Fc receptors of mouse mast cells were rapidly inactivated with a half-life of 9 min. Acidic conditions only slightly decreased the rate of inactivation. The Fc receptors of mouse erythrocytes and B cells were progressively inactivated, however, with half-lives of 24 and 60 min, respectively. The dissociation of the Fc receptors from mouse mast cells and of the Fc receptors from mouse erythrocytes was detectable on sodium dodecyl sulfate polyacrylamide gel electrophoresis as a loss of a protein (Mr = 44,000) and of the corresponding immunoprecipitable binding sites, respectively. Trypsin or chymotrypsin digestion of the Fc receptor from mouse erythrocytes reduced the electrophoretic mobility and the immunoprecipitable capacity, whereas digestion with proteases of low or no homology to these two proteases (such as V8, Pronase, and alpha-chymotrypsin) or with trypsin or chymotrypsin at neutral pH or through autoactivation of the trypsin molecule by the Fc receptor did not reduce the electrophoretic mobility of the Fc receptor. Proteinase K digestion of the Fc receptor of mouse mast cells reduced the electrophoretic mobility to below that of the denatured Fc receptor and destroyed immunoprecipitability. The inactivated Fc receptors lose their receptor binding capacity, however, presumably because the immunoglob
