laura, i'm familiar with both the hot and cold process. they both have their pros and cons. you can apply hot water directly to the skin, which might be more damaging. and yes, it's less than ideal. i'm not familiar with the cold process of internal cleansing. typically, if i want a purification. i use a process called enemas. it's like a colonic, which cleans out your bowels and then your bladder, sometimes. cold process was probably used to produce fermented wine in yeasts in the past. it's pretty disgusting, and i wouldn't recommend it. they are mostly used for production of rice and soya beans. china has plans to make it the main rice diet in its 1.3 billion people. now china is the world's largest producer of soya beans and is currently the world's largest producer and exporter of rice. in these meetings, students bring their reflections on the nature of their ideal 'human' communities, the ideal work situation, and the ideal workplace. they represent their responses in sketches, models, poems, words, and other media. there were six species of sloths in the time of darwin the dodo was not included in darwin's argument and in his book the voyage of beagle that the dodo is considered to be extinct by darwinists. it was first mentioned by mungo park, a scottish missionary travelling between sierra leone and gabon in the early 19th century, who told that it was believed to have gone into the eastern mountains of what is now called mozambique. park wrote the word "dodo" in his journal in symbols that supposedly came from an african language. he first tried to sell the story in london in 1823, but he gave no reliable information about the dodo. in 1824 he sent a letter to the zoological society of london, stating that he would send the specimens to england. the society was not interested, and in 1825 sent the specimens to england to the linnean society. in a letter to the secretary of the linnean society, george shaw, park gave a description of the dodo. he did not know its scientific name. he noted the symbols on the skeletons (which actually came from south america) as african writing. he reported that the animal was found on the islands of mauritius and rodriguez, in africa, and that was, in fact, its natural habitat.

the first protonemal filaments (shown here at five days after germination) were observed in the protocorms of the moss *fontinalis antipyretica* of Hjerting et al., 2001. New filaments begin to radiate from the growing colony, and soon the protocorm is obscured as the filaments rapidly increase in length. Filaments grow in the dark and divide until nearly all are interconnected. The moss then closes over itself, presumably to begin the process of photosynthesis. (These images were filmed on a +2% agar solidified fsw solution using a (frames-ok-1) digital microscope.)

**caption:** the rate of growth of filamentous protonemal filaments from moss colonies during the first five days of incubation on fsw agar was investigated by microscopically observing individual clones. After five days of growth, the rate of extension of these filaments in control colonies was 2.4 +/- 0.1 mm d(-1), equivalent to an average daily growth rate of 60% over five days. Growing colonies also extended significantly more filaments than static colonies. A recent revision of phylogenetic relationships among acrospermales has reclassified *fontinalis antipyretica* as part of the *fontinalis* group. This grouping includes the most basal moss taxon, *fontinalis*, which has been recognized for at least the last 265 million years. No previous study had used protocorms to estimate the evolutionary relationships of mosses. The inclusion of *fontinalis antipyretica* in the *fontinalis* group removes the longstanding taxonomic controversy concerning the relationships among acrospermales (Phs 2002). The new classification is based on similarities among the major morphological groups in the group, such as moss gametophyte anatomy (tetraphyrias, acrosoriates, crassidiadiegies) and reduced land plant characters. Only one major difference among the mosses in the *fontinalis* group involves their mode of reproduction. Gametophytes of the deciduous acrosoriphyllum species reproduce asexually by producing no more than a few somatic sporangia. The acrosoriphyllum species produce only zygospores by anastomosis. These results indicate that the *fontinalis* group may be the most basal clade within the acrosoriphyllales. Such an early divergence may suggest that extant mosses represent a potential time bomb. Indeed, the *fontinalis* group may have dramatically expanded after the Permian-Triassic extinction event, shortly after the origin of land plants. This hypothesis is consistent with the observation that the *fontinalis* group has persisted since the early Paleozoic, despite numerous mass extinctions in other groups of early land plants, including the spikemosses (Archaeplastida) and the Trigonophytes.
